

Bedford Public Schools

Grade 7 – Pre-Algebra

In 7th Grade Pre-Algebra, instructional time should focus on four critical areas: (1) developing understanding of and applying proportional relationships; (2) developing understanding of operations with rational numbers and working with expressions and linear equations; (3) solving problems involving scale drawings and informal geometric constructions, and working with two- and three-dimensional shapes to solve problems involving area, surface area, and volume; (4) drawing inferences about populations based on samples; (5) grasping the concept of a function and using functions to describe quantitative relationships; and (6) analyzing two- and three-dimensional space and figures using distance, angle, similarity, and congruence, and understanding and applying the Pythagorean Theorem.

Students extend their understanding of ratios and develop understanding of proportionality to solve single- and multi-step problems. Students use their understanding of ratios and proportionality to solve a wide variety of percent problems, including those involving discounts, interest, taxes, tips, and percent increase or decrease. Students solve problems about scale drawings by relating corresponding lengths between the objects or by using the fact that relationships of lengths within an object are preserved in similar objects. Students graph proportional relationships and understand the unit rate informally as a measure of the steepness of the related line, called the slope. They distinguish proportional relationships from other relationships.

Students develop a unified understanding of number, recognizing fractions, decimals (that have a finite or a repeating decimal representation), and percents as different representations of rational numbers. Students extend addition, subtraction, multiplication, and division to all rational numbers, maintaining the properties of operations and the relationships between addition and subtraction, and multiplication and division. By applying these properties, and by viewing negative numbers in terms of everyday contexts (e.g., amounts owed or temperatures below zero), students explain and interpret the rules for adding, subtracting, multiplying, and dividing with negative numbers. They use the arithmetic of rational

numbers as they formulate expressions and equations in one variable and use these equations to solve problems.

Students continue their work with area from grade 6, solving problems involving the area and circumference of a circle and surface area of three-dimensional objects. In preparation for work on congruence and similarity in grade 8 they reason about relationships among two-dimensional figures using scale drawings and informal geometric constructions, and they gain familiarity with the relationships between angles formed by intersecting lines. Students work with three-dimensional figures, relating them to two-dimensional figures by examining cross-sections. They solve real-world and mathematical problems involving area, surface area, and volume of two- and three-dimensional objects composed of triangles, quadrilaterals, polygons, cubes, and right prisms.

Students build on their previous work with single data distributions to compare two data distributions and address questions about differences between populations. They begin informal work with random sampling to generate data sets and learn about the importance of representative samples for drawing inferences.

Students grasp the concept of a function as a rule that assigns to each input exactly one output. They understand that functions describe situations where one quantity determines another. They can translate among representations and partial representations of functions (noting that tabular and graphical representations may be partial representations), and they describe how aspects of the function are reflected in the different representations.

Students use ideas about distance and angles, how they behave under translations, rotations, reflections, and dilations, and ideas about congruence and similarity to describe and analyze two-dimensional figures and to solve problems. Students show that the sum of the angles in a triangle is the angle formed by a straight line, and that various configurations of lines give rise to similar triangles because of the angles created when a transversal cuts parallel lines. Students understand the statement of the Pythagorean Theorem and its converse, and can explain why the Pythagorean Theorem holds, for example, by decomposing a square in two different ways. They apply the Pythagorean Theorem to find distances between points on the coordinate plane, to find lengths, and to analyze polygons. Students complete their work on volume by solving problems involving cones, cylinders, and spheres.

| <p>Analyze proportional relationships and use them to solve real-world and mathematical problems.</p> <ul style="list-style-type: none"> Proportionality can be represented in many ways, including percents, ratios, and rates. It shows a relationship between two values, a part to a part or a part to a whole. The relationship between a model and the actual object's dimensions is the scale, which is written as a ratio. A circle graph represents data as proportional parts of a circle. Rates are ratios of two quantities with different units. You can use ratios to find equivalent rates and unit rates. Unit rates are useful for comparisons. Cross-products can be used to solve proportions. A percent is a ratio with a denominator of 100. You can write a percent as a decimal or as a fraction. Finding the percent of change requires understanding the increase or decrease. | <ul style="list-style-type: none"> How are constants of proportionality reflected in scale factor, slope and the graph of a linear equation? What happens if the proportionality of a model is not maintained? How does your understanding of ratios impact your effectiveness as a shopper? Why are unit rates important for comparisons? How do you solve a proportion with the cross products property? How do you find the percent one number is of another number using a proportion? Why is differentiating between part-to-part ratios and part-to-whole ratios critical for comparisons? How are ratios and rates similar and different? | <ul style="list-style-type: none"> Find ratios and unit rates Find equivalent rates Write and solve proportions Solve percent problems using proportions Rewrite and convert fractions, decimals, and percents Order decimals, fractions, and percents Solve percent problems with percent increase/decrease. Solve percent problems using the percent equation Understand and calculate discount, markup, tax, and simple interest Add, subtract, multiply, and divide using fractions, decimals, or percents Apply scale factor appropriately in different dimensions (length, area, volume) Find the equation of a line from a graph, table, point and slope, or two points | <ul style="list-style-type: none"> Chapter 4.8/7 (Scientific Notation, Metric Conversion and Ratios/Proportions/ Percents) Test 7.RP.1, 7.RP.2.a, 7.RP.2b, 7.RP.2c, 7.RP.3, 7.NS.2d Chapter 11 (Linear Equations and Graphs) Quest7.EE.4a, 7.RP.2d, 8.F.1, 8.F.3, 8.F.4 |
